

PHYS 1444 – Section 004

Lecture #18

Monday, April 9, 2012

*Dr. **Jaehoon** Yu*

- Induction of EMF
- Electric Generators
- DC Generator
- Eddy Currents
- Transformer

Today's homework is #11, due 10pm, Tuesday, Apr. 17!!

Announcements

- Term exam #2
 - Non-comprehensive
 - Date and time: 5:30 – 6:50pm, Wednesday, Apr. 25
 - Location: SH103
 - Coverage: CH. 27 – 1 to what we finish Monday, Apr. 23
 - Please do NOT miss the exam!!
- Reading assignments
 - CH29 – 5 and CH29 – 8
- No colloquium this week

Special Project #5

- **B due to current I in a straight wire.** For the field near a long straight wire carrying a current I , show that
 - (a) The Ampere's law gives the same result as the simple long straight wire, $B=\mu_0 I/2\pi R$. (10 points)
 - (b) That Biot-Savart law gives the same result as the simple long straight wire, $B=\mu_0 I/2\pi R$. (10 points)
- Must be your OWN work. No credit will be given for copying straight out of the book, lecture notes or from your friends' work.
- Due is at the beginning of the class on Wednesday, Apr. 18.

Induction of EMF

- How can we induce emf?
- Let's look at the formula for the magnetic flux
- $\Phi_B = \int \vec{B} \cdot d\vec{A} = \int B \cos \theta dA$
- What do you see? What are the things that can change with time to result in change of magnetic flux?

– Magnetic field

– The area of the loop

– The angle θ between the field and the area vector

Monday, Apr. 9, 2012

PHYS 1444-004, Spring 2012 Dr.
Jaehoon Yu

Example 29 – 5

Pulling a coil from a magnetic field. A square coil of wire with side 5.00cm contains 100 loops and is positioned perpendicular to a uniform 0.600-T magnetic field. It is quickly and uniformly pulled from the field (moving perpendicular to B) to a region where B drops abruptly to zero. At $t=0$, the right edge of the coil is at the edge of the field. It takes 0.100s for the whole coil to reach the field-free region. Find (a) the rate of change in flux through the coil, (b) the emf and current induced, and (c) how much energy is dissipated in the coil if its resistance is 100Ω . (d) what was the average force required?

What should be computed first? The initial flux at $t=0$.

The flux at $t=0$ is $\Phi_B = \vec{B} \cdot \vec{A} = BA = 0.600T \cdot (5 \times 10^{-2} m)^2 = 1.50 \times 10^{-3} Wb$

The change of flux is $\Delta\Phi_B = 0 - 1.50 \times 10^{-3} Wb = -1.50 \times 10^{-3} Wb$

Thus the rate of change of the flux is

$$\frac{\Delta\Phi_B}{\Delta t} = \frac{-1.50 \times 10^{-3} Wb}{0.100s} = -1.50 \times 10^{-2} Wb/s$$

Example 29 – 5, cnt'd

Thus the total emf induced in this period is

$$\varepsilon = -N \frac{d\Phi_B}{dt} = -100 \cdot (-1.50 \times 10^{-2} \text{ Wb/s}) = 1.5V$$

The induced current in this period is

$$I = \frac{\varepsilon}{R} = \frac{1.5V}{100\Omega} = 1.50 \times 10^{-2} \text{ A} = 15.0mA$$

Which direction would the induced current flow? Clockwise

The total energy dissipated is

$$E = Pt = I^2 R t = (1.50 \times 10^{-2} \text{ A})^2 \cdot 100\Omega \cdot 0.100s = 2.25 \times 10^{-3} \text{ J}$$

Force for each coil is $\vec{F} = I\vec{l} \times \vec{B}$ Force for N coil is $\vec{F} = N I\vec{l} \times \vec{B}$

$$|F| = N I l B = 100 \cdot (1.50 \times 10^{-2} \text{ A}) \cdot (4 \times 5 \times 10^{-2}) \cdot 0.600T = 0.045N$$

EMF Induced on a Moving Conductor

- Another way of inducing emf is using a U shaped conductor with a movable rod resting on it.
- As the rod moves at a speed v , it travels $v dt$ in time dt , changing the area of the loop by $dA = \ell v dt$.
- Using Faraday's law, the induced emf for this loop is

$$|\mathcal{E}| = \frac{d\Phi_B}{dt} = \frac{B dA}{dt} = \frac{B \ell v dt}{dt} = B \ell v$$

- This equation is valid as long as B , ℓ and v are perpendicular to each other. What do we do if not?
 - Use the scalar product of vector quantities
- An emf induced on a conductor moving in a magnetic field is called a **motional emf**

Electric Generators

- What does a generator do?
 - Transforms mechanical energy into the electrical energy
 - What does this look like?
 - An inverse of an electric motor which transforms electrical energy to mechanical energy
 - An electric generator is also called a dynamo
- Whose law does the generator based on?
 - Faraday's law of induction

How does an Electric Generator work?

- An electric generator consists of
 - Many coils of wires wound on an armature that can rotate by mechanical means in a magnetic field
- An emf is induced in the rotating coil
- Electric current is the output of a generator
- Which direction does the output current flow when the armature rotates counterclockwise?
 - The conventional current flows outward on wire A toward the brush
 - After half the revolution the wire A will be where the wire C is and the current flow on A is reversed
- Thus the current produced is alternating its direction

How does an Electric Generator work?

- Let's assume the loop is rotating in a uniform B field w/ a constant angular velocity ω . The induced emf is

- $$\varepsilon = -\frac{d\Phi_B}{dt} = -\frac{d}{dt} \int \vec{B} \cdot d\vec{A} = -\frac{d}{dt} [BA \cos \theta]$$

- What is the variable that changes above?

- The angle θ . What is $d\theta/dt$?

- The angular speed ω .

- So $\theta = \theta_0 + \omega t$

- If we choose $\theta_0 = 0$, we obtain

- $$\varepsilon = -BA \frac{d}{dt} [\cos \omega t] = BA\omega \sin \omega t$$

- If the coil contains N loops:
$$\varepsilon = -N \frac{d\Phi_B}{dt} = NBA\omega \sin \omega t = \varepsilon_0 \sin \omega t$$

- What is the shape of the output?

- Sinusoidal w/ amplitude $\varepsilon_0 = NBA\omega$

- USA frequency is 60Hz. Europe is at 50Hz

- Most the U.S. power is generated at steam plants

Source: U.S. Energy Information Administration, *Monthly Energy Review* (June 2011). Percentages based on Table 7.2a, preliminary 2010 data.

The World Energy Consumption

- In 2008, total worldwide energy consumption was 474 EJ (474×10^{18} J = 132,000 TWh).
 - Equivalent to an average energy consumption rate of 15 terawatts (1.504×10^{13} W)
- The potential for renewable energy
 - solar energy 1600 EJ (444,000 TWh)
 - wind power 600 EJ (167,000 TWh)
 - geothermal energy 500 EJ (139,000 TWh),
 - biomass 250 EJ (70,000 TWh)
 - hydropower 50 EJ (14,000 TWh) an
 - ocean energy 1 EJ (280 TWh)

Example 29 – 9

An AC generator. The armature of a 60-Hz AC generator rotates in a 0.15-T magnetic field. If the area of the coil is $2.0 \times 10^{-2} \text{m}^2$, how many loops must the coil contain if the peak output is to be $\epsilon_0 = 170 \text{V}$?

The maximum emf of a generator is $\epsilon_0 = N B A \omega$

Solving for N $N = \frac{\epsilon_0}{B A \omega}$

Since $\omega = 2\pi f$ We obtain

$$N = \frac{\epsilon_0}{2\pi B A f} = \frac{170 \text{V}}{2\pi \cdot (0.15 \text{T}) \cdot (2.0 \times 10^{-2} \text{m}^2) \cdot (60 \text{s}^{-1})} = 150 \text{turns}$$
