1. Collisions in Two Dimension
2. Center of Mass
   • Definition
   • CM of a Rigid Object
   • Center of Mass and Center of Gravity
3. Motion of a Group of Particles
4. Rocket Propulsion
5. Fundamentals on Rotation

Today's homework is homework #12, due 12:00pm, next Monday!!
Announcements

- **2nd Term exam**
  - *Wednesday, Oct. 30*, in the class
  - Covers chapters 6 – 10
  - Mixture of Multiple choice and Essay problems
  - Review on Monday, Oct. 28

- Magda Cortez, please come and talk to me after the class
Two dimensional Collisions

In two dimension, one can use components of momentum to apply momentum conservation to solve physical problems.

\[ m_1 \vec{v}_{1i} + m_2 \vec{v}_{2i} = m_1 \vec{v}_{1f} + m_2 \vec{v}_{2f} \]  
\[ m_1 v_{1ix} + m_2 v_{2ix} = m_1 v_{1fx} + m_2 v_{2fx} \]
\[ m_1 v_{1iy} + m_2 v_{2iy} = m_1 v_{1fy} + m_2 v_{2fy} \]

Consider a system of two particle collisions and scatters in two dimension as shown in the picture. (This is the case at fixed target accelerator experiments.) The momentum conservation tells us:

\[ m_1 \vec{v}_{1f} + m_2 \vec{v}_{2f} = m_1 \vec{v}_{1i} \]
\[ m_1 v_{1ix} = m_1 v_{1fx} + m_2 v_{2fx} = m_1 v_{1f} \cos \theta + m_2 v_{2f} \cos \phi \]
\[ m_1 v_{1iy} = 0 = m_1 v_{1fy} + m_2 v_{2fy} = m_1 v_{1f} \sin \theta - m_2 v_{2f} \sin \phi \]

And for the elastic conservation, the kinetic energy is conserved:

\[ \frac{1}{2} m_1 v_{1i}^2 = \frac{1}{2} m_1 v_{1f}^2 + \frac{1}{2} m_2 v_{2f}^2 \]

What do you think we can learn from these relationships?
Example 9.9

A 1500kg car traveling east with a speed of 25.0 m/s collides at an interaction with a 2500kg van traveling north at a speed of 20.0 m/s. After the collision the two cars stuck to each other, and the wreckage is moving together. Determine the velocity of the wreckage after the collision, assuming the vehicles underwent a perfectly inelastic collision.

The initial momentum of the two car system before the collision is

\[
\vec{p}_i = m_1 v_{1i} \hat{i} + m_2 v_{2i} \hat{j} = 1500 \times 25.0 \hat{i} + 2500 \times 20.0 \hat{j}
\]

\[
= 3.75 \times 10^4 \hat{i} + 5.0 \times 10^4 \hat{j}
\]

The final momentum of the two car system after the perfectly inelastic collision is

\[
\vec{p}_f = (m_1 + m_2) (v_{fx} \hat{i} + v_{fy} \hat{j}) = 4.0 \times 10^3 v_{fx} \hat{i} + 4.0 \times 10^3 v_{fy} \hat{j}
\]

Using momentum conservation

- **X-comp.**
  \[
p_{fx} = p_{ix}
  \]
  \[
  (m_1 + m_2)v_{fx} = m_1 v_{1x} + 0
  \]
  \[
  v_{fx} = \frac{(m_1 v_{1x} + 0)}{m_1 + m_2} = \frac{3.75 \times 10^4}{1500 + 2500} = 9.38 \text{ m/s}
  \]

- **Y-comp.**
  \[
p_{fy} = p_{iy}
  \]
  \[
  (m_1 + m_2)v_{fy} = 0 + m_2 v_{2y}
  \]
  \[
  v_{fy} = \frac{0 + m_2 v_{2y}}{m_1 + m_2} = \frac{5.0 \times 10^4}{1500 + 2500} = 12.5 \text{ m/s}
  \]

The final velocity of the wreckage is

\[
\vec{v}_f = v_{fx} \hat{i} + v_{fy} \hat{j} = \left(9.38 \hat{i} + 12.5 \hat{j}\right) \text{m/s}
\]
Example 9.10

Proton #1 with a speed $3.50 \times 10^5$ m/s collides elastically with proton #2 initially at rest. After the collision, proton #1 moves at an angle of $37^\circ$ to the horizontal axis and proton #2 deflects at an angle $\phi$ to the same axis. Find the final speeds of the two protons and the scattering angle of proton #2, $\phi$.

Since both the particles are protons $m_1 = m_2 = m_p$. Using momentum conservation, one obtains

**x-comp.** $m_p v_{1i} = m_p v_{1f} \cos \theta + m_p v_{2f} \cos \phi$

**y-comp.** $m_p v_{1f} \sin \theta - m_p v_{2f} \sin \phi = 0$

Canceling $m_p$ and put in all known quantities, one obtains

1. $v_{1f} \cos 37^\circ + v_{2f} \cos \phi = 3.50 \times 10^5$ (1)
2. $v_{1f} \sin 37^\circ = v_{2f} \sin \phi$ (2)

Solving Eqs. 1-3 equations, one gets

$$v_{1f} = 2.80 \times 10^5 \text{ m/s}$$

$$v_{2f} = 2.11 \times 10^5 \text{ m/s}$$

$$\phi = 53.0^\circ$$
Center of Mass

We've been solving physical problems treating objects as sizeless points with masses, but in realistic situations objects have shapes with masses distributed throughout the body.

Center of mass of a system is the average position of the system's mass and represents the motion of the system as if all the mass is on the point.

What does above statement tell you concerning forces being exerted on the system?

The total external force exerted on the system of total mass M causes the center of mass to move at an acceleration given by $\vec{a} = \sum \vec{F} / M$ as if all the mass of the system is concentrated on the center of mass.

Consider a massless rod with two balls attached at either end. The position of the center of mass of this system is the mass averaged position of the system

$$x_{CM} \equiv \frac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$$

CM is closer to the heavier object
Center of Mass of a Rigid Object

The formula for CM can be expanded to Rigid Object or a system of many particles

\[
x_{CM} = \frac{m_1x_1 + m_2x_2 + \cdots + m_nx_n}{m_1 + m_2 + \cdots + m_n} = \sum_i m_i x_i \quad \sum m_i
\]

\[
y_{CM} = \frac{\sum m_i y_i}{\sum m_i} \quad z_{CM} = \frac{\sum m_i z_i}{\sum m_i}
\]

The position vector of the center of mass of a many particle system is

\[
\vec{r}_{CM} = x_{CM} \hat{i} + y_{CM} \hat{j} + z_{CM} \hat{k} = \frac{\sum m_i \vec{r}_i}{\sum m_i}
\]

A rigid body – an object with shape and size with mass spread throughout the body, ordinary objects – can be considered as a group of particles with mass \(m_i\) densely spread throughout the given shape of the object
The net effect of these small gravitational forces is equivalent to a single force acting on a point (Center of Gravity) with mass $M$.

**Center of Mass and Center of Gravity**

The center of mass of any symmetric object lies on an axis of symmetry and on any plane of symmetry, if object’s mass is evenly distributed throughout the body.

**Center of Gravity**

How do you think you can determine the CM of objects that are not symmetric?

1. Hang the object by one point and draw a vertical line following a plum-bob.
2. Hang the object by another point and do the same.
3. The point where the two lines meet is the CM.

Since a rigid object can be considered as **collection of small masses**, one can see the total gravitational force exerted on the object as

$$
\vec{F}_g = \sum_i \vec{F}_i = \sum_i \Delta m_i \vec{g} = M \vec{g}
$$

The net effect of these small gravitational forces is equivalent to a single force acting on a point (Center of Gravity) with mass $M$. 
Example 9.12

A system consists of three particles as shown in the figure. Find the position of the center of mass of this system.

Using the formula for CM for each position vector component:

\[
\vec{r}_{CM} = \frac{\sum m_i x_i}{\sum m_i} \hat{i} + \frac{\sum m_i y_i}{\sum m_i} \hat{j}
\]

One obtains

\[
\vec{r}_{CM} = (0.75, 4) \quad \text{kg m}
\]

If \( m_1 = 2 \text{ kg}; m_2 = m_3 = 1 \text{ kg} \)

\[
\vec{r}_{CM} = \frac{3\hat{i} + 4\hat{j}}{4} = 0.75\hat{i} + \hat{j}
\]
Example 9.13

Show that the center of mass of a rod of mass $M$ and length $L$ lies in midway between its ends, assuming the rod has a uniform mass per unit length.

The formula for CM of a continuous object is

$$x_{CM} = \frac{1}{M} \int_{x=0}^{x=L} x \, dm$$

Since the density of the rod ($\lambda$) is constant; $\lambda = M/L$

The mass of a small segment $\, dm = \lambda \, dx$

Therefore

$$x_{CM} = \frac{1}{M} \int_{x=0}^{x=L} \lambda x \, dx = \frac{1}{M} \left[ \frac{1}{2} \lambda x^2 \right]_{x=0}^{x=L} = \frac{1}{M} \left( \frac{1}{2} \lambda L^2 \right) = \frac{1}{M} \left( \frac{1}{2} ML \right) = \frac{L}{2}$$

Find the CM when the density of the rod non-uniform but varies linearly as a function of $x$, $\lambda = \alpha x$

$$M = \int_{x=0}^{x=L} \lambda \, dx = \int_{x=0}^{x=L} \alpha x \, dx = \left[ \frac{1}{2} \alpha x^2 \right]_{x=0}^{x=L} = \frac{1}{2} \alpha L^2$$

$$x_{CM} = \frac{1}{M} \int_{x=0}^{x=L} \lambda x \, dx = \frac{1}{M} \int_{x=0}^{x=L} \alpha x^2 \, dx = \frac{1}{M} \left[ \frac{1}{3} \alpha x^3 \right]_{x=0}^{x=L}$$

$$x_{CM} = \frac{1}{M} \left( \frac{1}{3} \alpha L^3 \right) = \frac{1}{M} \left( \frac{2}{3} ML \right) = \frac{2L}{3}$$

Motion of a Group of Particles

We’ve learned that the CM of a system can represent the motion of a system. Therefore, for an isolated system of many particles in which the total mass $M$ is preserved, the velocity, total momentum, acceleration of the system are

- **Velocity of the system**
  \[
  \vec{v}_{CM} = \frac{d\vec{r}_{CM}}{dt} = \frac{d}{dt}\left(\frac{1}{M} \sum m_i \vec{r}_i\right) = \frac{1}{M} \sum m_i \frac{d\vec{r}_i}{dt} = \frac{\sum m_i \vec{v}_i}{M}
  \]

- **Total Momentum of the system**
  \[
  \vec{p}_{CM} = M \vec{v}_{CM} = M \left(\sum m_i \vec{v}_i\right) = \sum m_i \vec{v}_i = \sum \vec{p}_i = \vec{p}_\text{tot}
  \]

- **Acceleration of the system**
  \[
  \vec{a}_{CM} = \frac{d\vec{v}_{CM}}{dt} = \frac{d}{dt}\left(\frac{1}{M} \sum m_i \vec{v}_i\right) = \frac{1}{M} \sum m_i \frac{d\vec{v}_i}{dt} = \frac{\sum m_i \vec{a}_i}{M}
  \]

- **External force exerting on the system**
  \[
  \sum \vec{F}_{ext} = M \vec{a}_{CM} = \sum m_i \vec{a}_i = \frac{d\vec{p}_{tot}}{dt}
  \]

- **If net external force is 0**
  \[
  \sum \vec{F}_{ext} = 0 = \frac{d\vec{p}_{tot}}{dt} \quad \Rightarrow \quad \vec{p}_{tot} = \text{const}
  \]

- **System’s momentum is conserved.**
